

LBSystem::is_disabled(\$text)

\$bool = is_disabled(\$text);

Used for config parameters. Returns True if the \$text contains a word that fuzzy could mean *False*. If the passed string contains one of these words:

false, no, off, disabled, disable, 0

The function will return True, otherwise False.

The keyword search is case *ir*sensitive.

This is *not* a inversion of is_enabled.

The intention of the is_disabled function is to query a config parameter for a feature that is normally enabled. If it is not explicitly disabled, you default to enable it.
